

PLANKTONIC FORAMINIFERAL ASSEMBLAGES AND MERIDIONAL HYDROGRAPHIC SECTIONS IN THE WEST PACIFIC OCEAN

Akio HATTA, Yasutaka YUWAKI, Toru NISHI,
Sunao MASUMITSU and Masataka HIGASHI

Introduction

Oceanographical surveys and studies of planktonic foraminiferal assemblage were carried out in Nov. 1989. Plankton were collected in the west Pacific on a voyage from Kagoshima, Japan to Lae in Papua New Guinea, and the water temperature and salinity were noted.

The basic purpose of this study was to consider the ecology and environment of living planktonic foraminifera. Recent planktonic foraminifera provide much information on fossils, and fossils of planktonic foraminifera preserved in strata are very important when considering the geological age and palaeoecology of the strata.

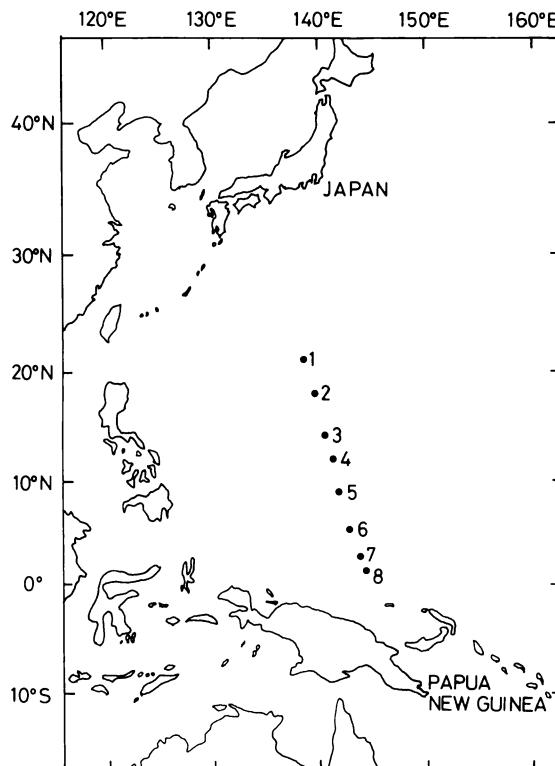

Fig. 1. Sampling stations in the West Pacific Ocean.

Previous Work

Planktonic foraminifera were discovered over a century ago and have been used for biostratigraphic analysis. D'ORBIGNY was the first researcher to describe the planktonic foraminifera from the beach sands of Cuba and Canary Islands in 1826 and 1839 (HEMLEBEN et al., 1989).

In 1884, BRADY reported on planktonic foraminifera collected by the H.M.S. Challenger from the north and south Pacific (BARKER, 1960), and since then living planktonic foraminifera have been studied by many researchers. BRADSHAW (1959) made a study of the ecology of living planktonic foraminifera in the north and equatorial Pacific. PARKER (1962) made a taxonomic study considering variations and intergradations, and discussed some of the planktonic species in the Recent sediment of the eastern half of the south Pacific. UJIÉ (1968) investigated the distribution of each species of living planktonic foraminifera from the southeast Indian Ocean. BÉ (1977) made a study from the ecological and zoogeographical points of view, and reviewed the taxonomy of Recent planktonic foraminifera. LIPPS (1979) studied the ecology and palaeoecology of planktonic foraminifera. SAITO et al. (1981) studied systematically the Recent and Pleistocene planktonic foraminifera. HATTA and HAYASAKA (1987) made a preliminary study of the distribution of planktonic foraminifera in the west Pacific. HEMLEBEN et al. (1989) have completed the most recent study of modern planktonic foraminifera.

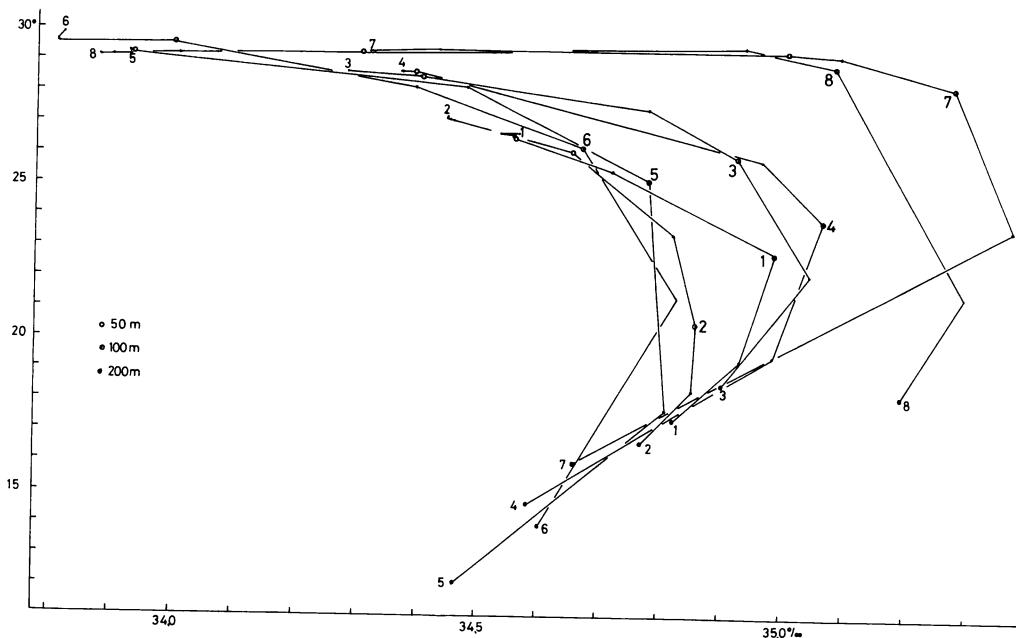

Fig. 2. Temperature and salinity of eight stations in the West Pacific Ocean.

Table 1. Observation data: sampling position, date, operation hour, salinity and water temperature.

Sampling Methods and Materials

Sampling stations are shown in Fig. 1. The eight stations extended from Lat. 21° N, Long. 138° E to 1° N, 144° E. At each sampling station, we collected four samples by vertical towing between depth of 200 and 150 m, 150 and 100 m, 100 and 50 m, 50 and 0 m. The dates, operation hours, sampling positions, salinity, and temperatures of the sea water are shown in Table 1. At each sampling station, it took about one and a half hours to collect four samples.

The temperature-salinity ratio of each station is indicated in Fig. 2. It can be seen that the ratios for stations 7 and 8 are slightly different from the others.

Features of Planktonic Foraminiferal Assemblage

32 samples of fresh planktonic foraminifera have been examined. Table 2 is a list of planktonic foraminifera from 8 sampling stations.

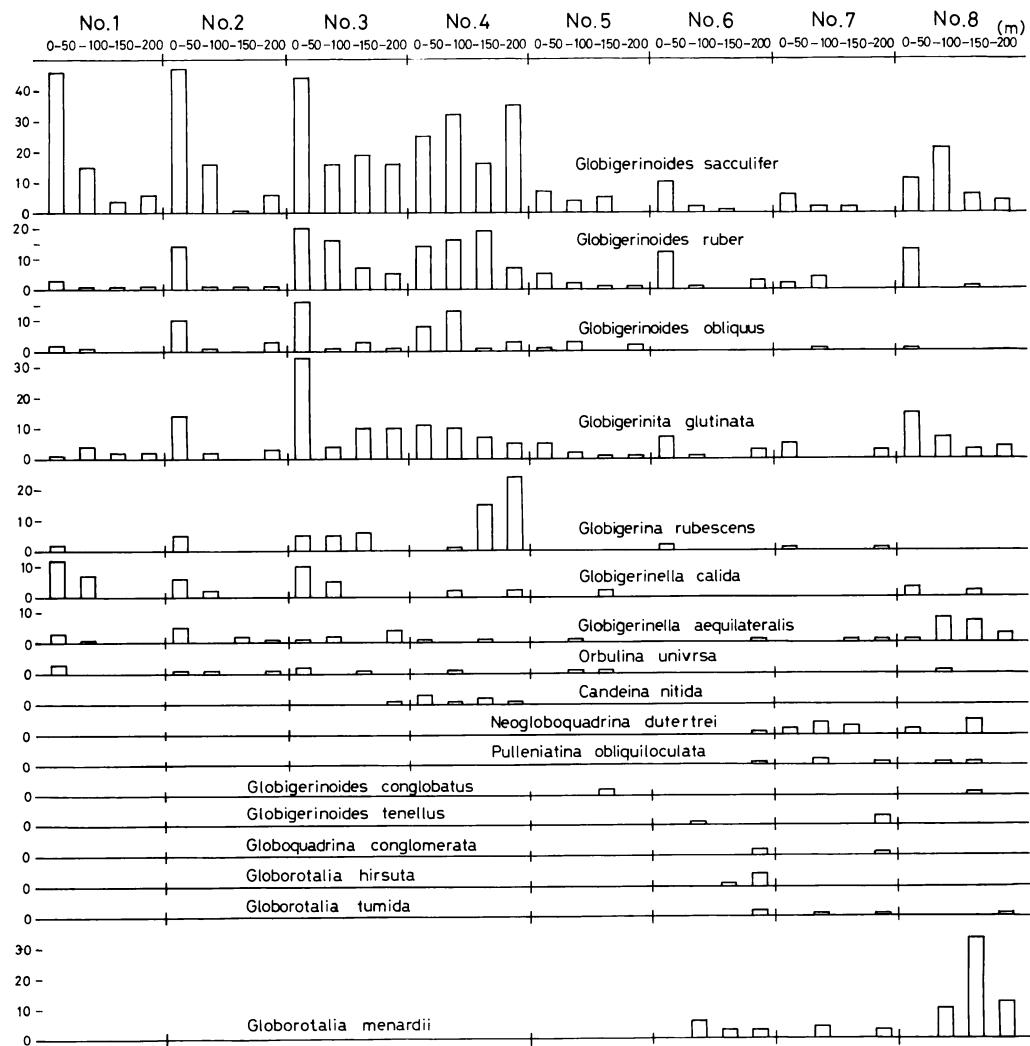

Fig. 3. Frequency distribution of planktonic foraminifera from each sampling zone.

Table 2. Planktonic Foraminifera at stations No. 1 to No. 8.

The following species were found in every sample : *Globigerinoides sacculifer* (BRADY), *G. ruber* (D'ORBIGNY), and *Globigerinita glutinata* EGGER. *Candeina nitida* D'ORBIGNY was found only in samples from stations No. 3 and 4.

Globorotalia menardii (PARKER, JONES & BRADY), *G. tumida* (BRADY), *Neogloboquadrina dutertrei* (D'ORBIGNY), and *Pulleniatina obliquiloculata* (D'ORBIGNY) were contained only in the sample from station No. 6.

The frequency distribution of each species from every sampling zone is shown in Fig. 3.

Results

Distinct differences were found in planktonic foraminiferal assemblage between the northern region of station No. 5 and southern region of No. 6. The temperature and salinity of seawater at stations No. 7 and 8 distinguish them from other stations. There was also a little difference between the distribution of planktonic foraminiferal assemblage and of sea water.

Globigerinoides sacculifer, *G. ruber*, *G. obliquus* and *Globigerinita glutinata* were conspicuously abundant in the 0–50 m zone during the day (stations No. 1 and 2) and became abundant in the 50–200 m zone at night (station No. 4). *Globorotalia menardii* was abundant in the 50–200 m zone but absent from the 0–50 m zone at three stations (No. 6, 7 and 8). *Candeina nitida* was found at only two stations (No. 3 and 4).
