Redescriptions of Three Species of the Genus Asteralobia (Diptera, Cecidomyiidae)

Junichi Yukawa

(Entomological Laboratory)
Received for Publication September 1, 1982

Introduction

When the Japanese species of the supertribe Asphondyliidi were revised in Yukawa¹⁴⁾, four species of the genus Asphondylia were not redescribed, being temporarily placed in that genus, which was chiefly due to a lack of adult specimens to be examined. Thereafter, the present author had some opportunities to obtain the specimens of these species from various localities in Japan. One of the species, Asphondylia sphaera Monzen⁶⁾ was confirmed to be placed in the genus to which it had originally been referred, and was redescribed together with notes on its bionomics¹⁸⁾. The generic status of the remaining three species, Asphondylia humuli Shinji⁸⁾, Asphondylia patriniae (Shinji)⁷⁾ and Asphondylia styraci Shinji¹⁰⁾ has been kept in doubt, with their exclusion from the species list of the Japanese Asphondylia^{17, 19)}.

The present paper is intended to combine the three species with a proper genus and to redescribe them in the light of the recent taxonomic studies.

Materials and Methods

The specimens examined here were obtained by dissecting and rearing midge galls collected from various parts of Japan during the period from 1971 to 1981. In preparing microscope slides, the author adopted the xylene-balsam method, and drawings were made with the aid of a camera lucida. Wing length was measured from the basal end of costa to apex. Setal counts are of setal insertions rather than of actual setae, since many setae come to be lost through the processes of collection, preservation and preparation.

Unfortunately, the type specimens of the three species described by Shinji^{7,8,10)} have been lost. Therefore, the specimens reared from the galls similar to those described by him were examined instead of the types, and neotypes of the species are newly designated in this paper. The slide-mounted specimens including the neotypes are kept in the collection of the Entomological Laboratory of the Kagoshima University in Kagoshima, Japan.

Genus Asteralobia Kovalev

Asteralobia Kovalev, 1964. Ent. Obozr. 43: 419.

Type-species, Asteralobia doellingeriae Kovalev⁴).

Asteralobia Kovalev: Yukawa¹⁴⁾.

The genus Asteralobia is closely related to the genus Schizomyia Kieffer¹⁾ [= Parasphondylia

Kieffer²⁾] in respect of male genitalia, ovipostior and many other adult and larval features. The former is, however, distinguishable from the latter by having male flagellomeres constricted shallowly and divided into 3 parts (subgenus *Asteralobia*), or by having those the lower constriction of which forms a neck between the basal and distal enlargements of the respective flagellomere (subgenus *Euasteralobia*).

Other generic characters are summarized as follows: palpi consisting of 1 + 4 segments, with setae moderate in number; antenna with 2 + 12 segments in both sexes; scape larger than pedicel, both with more numerous setae ventrally; length of each flagellomere successively a little shortened distally in male, successively shortened distally and terminal one subglobular in female; basal enlargement of female flagellomeres not distinctly constricted; tarsomere 1 with a minute apical lobe not extending beyond distal end of the segment; tarsal claws simple on all legs, bent nearly at right angle on distal third; vein R₅ meeting with costa nearly at wing apex. Seventh abdominal segment of female with a chitinized ventral sclerite. Male genitalia showing a typical shape of Asteralobia; cerci incised by a V-shaped emargination, forming a pair of lobes which are rounded on outer margin; hypoproct slender, distally incised by an U-shaped emargination, forming a pair of narrow lobes, each of which has an apical seta; gonostylus relatively short, slightly curved inwardly, ending ventro-

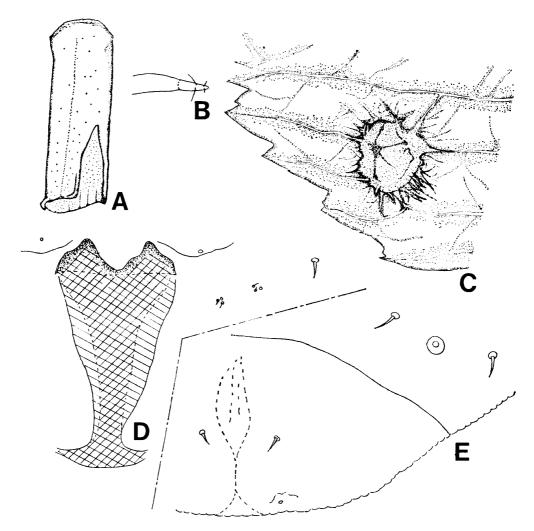

Fig. 1. Asteralobia humuli (Shinji). A: Tarsomere 1 of hind leg; B: Minute apical lobe of ovipositor with cilia; C: Gall produced on hypophyllous portion of leaf vein; D: Sternal spatula of mature larva; E: Dorsal surface of eighth and ninth abdominal segments of mature larva.

distally in an acute angle, with a dense group of short, stiff setae subdistally; gonocoxite elongated, ventro-distally developed into a large setose lobe, with a finger-like medio-basal lobes; root of gonocoxite relatively short; aedeagus slender, laterally weakly sclerotized, distally tapering. Ovipositor protractile, slender, aciculate, basally with a small dorsal lobe.

Asteralobia humuli (Shinji) new combination

Figs. 1(A-E), 2(A-C); Tables 1-3.

Asphondylia humuli Shinji^{8,9)}.

Parasphondylia humuli Shinji: Shinji¹⁰⁾.
Asphondylia humuli Shinji: Yukawa^{14,15)}.

English name: Humulus leaf gall midge, new name

Japanese name: "Kanamugura-nise-hario-tamabae" Shinji10)

(="Kanamugura-hario-tamabae" Shinji8; "Yaemugura-hario-tamabae" Shinji8)

Male: Eye bridge 7 to 8 facets wide medially. Post vertical peak very low. Flagellomeres dark brown; distal stem of each flagellomere without microtrichea; flagellomeres 1 and 2 fused. Thorax reddish brown on dorsum, orange on sides. Coxa and basal 2/3 of femur pale brown; remainder parts of legs with dark greyish hairs densely; empodium about 2/3 as long as claw. Wing length 1.78 to 1.90 mm, 2.3 to 2.6 times as long as maximum width. Male genitalia showing a typical shape of Asteralobia.

Female: Wing length 1.80 to 2.05 mm, about 2.6 times as long as maximum width. Ovipositor pale brown; minute apical lobe of ovipositor with a few short cilia. Otherwise almost as in male.

Mature larva: Second antennal segment short, conical, about $12 \mu m$, 1.6 to 1.7 times as long as basal width; cervical papillae all without seta. Number and position of spiracles normal; 6 dorsal and 2 (sometimes 3) pleural papillae each with a seta; 2 dorsal papillae of eighth abdominal segment each with a seta; 2 of 8 terminal papillae not sclerotized, each with a seta; remaining 6 terminal papillae inconspicuous, probably without seta, if present. Sternal spatula 160 to 200 μm in length, 2.0 to 2.6 times as long as maximum width, distally emarginated, forming a pair of triangular lobes; number and position of inner and outer lateral papillae normal; sternal papillae without seta on all thoracic segments; inner pleural papillae without seta on prothorax, each with a seta on meso- and metathorax; usually 4 anterior ventral papillae without seta; 2 posterior ventral papillae each with a seta; 4 ventral papillae of eighth abdominal segment without seta; 4 anal papillae visible, each without seta.

Pupa: Apical spine relatively short, 45 to 50 μ m, rounded apically; seta of apical papillae about 75 μ m; anterior (upper) and posterior (lower) frontal spines absent; usually 1 of 2 pairs of posterior (lower) facilal papillae and 1 of 3 pairs of lateral facial papillae each with a seta; prothoracic horn relatively long, 260 to 310 μ m; stigma short, 16 to 23 μ m, present on second to sixth abdominal segments; each abdominal segment except first and terminal ones dorsally with 2 or 3 transvers rows of spines of anterior third; usually 2 of 5 dorsal papillae each with a short seta.

Host plants: Humulus japonicus Sieb. et Zucc." Kanamugura", Humulus lupulus L. var. cordifolius (Miq.) Maxim. "Karahanaso" [Moraceae].

Gall: Subglobular or ellipsoidal swelling normally on the hypophyllous portion of leaf veins, sometimes on the flower bud, peduncle or on the epiphyllous portion of leaf veins; surface white or pale yellow, with white hairs, sometimes with a reddish tinge; major axis 1.7 to 5.0 mm, minor axis

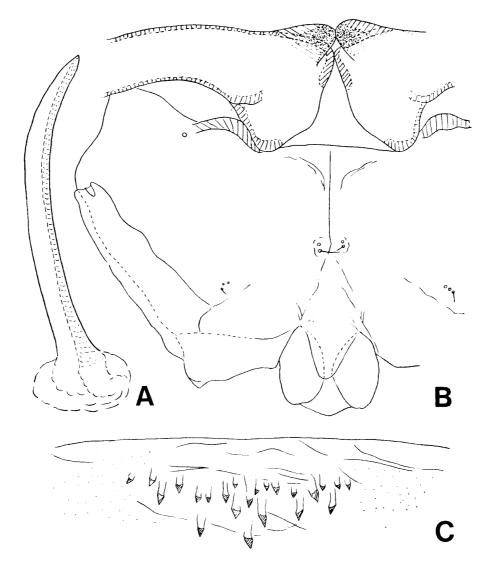

Fig. 2. Asteralobia humuli (Shinji). A: Prothoracic horn of pupa; B: Basal portion of antennal sheath and frontal area of pupa; C: Spines on dorsal surface of sixth abdominal segment of pupa.

1.2 to 3.0 mm, height 1.0 to 2.2 mm; monothalamus; each gall containing normally 1, rarely 2 midge larvae; number of galls per leaf normally ranging from 1 to 12; sometimes 2 or 3 galls produced continuously. Japanese name of the gall; "Kanamugura-haura-fushi" Shinji¹⁰⁾; Yukawa¹⁵⁾.

Biological notes: According to Shinji⁸⁾, there are 2 generations a year (probably in Morioka Iwate pref.). Larvae of the second generation escape from the galls to hibernate in the soil, and adults emerge in July of the following year. Later, Shinji¹⁰⁾ stated that the species repeated 3 generations a year (probably in Tokyo or its vicinity). The present study also reveals that this species has at least 3 generations a year from June to September in southern Kyushu. A species of europhid parasitoid emerged from the gall obtained in Hayato, Kaogshima pref. (see data of collection), but it has not been identified yet.

Slide-mounted specimens examined: Neotype \mathfrak{P} , gall collected from Toso, Kagoshima city, 17. VIII. 1971, J. Yukawa leg., host: *Humulus japonicus*, emerged on 24. VIII. 1971, reared by J. Yukawa, Cecid. No. B9101. 1 \mathfrak{P} , 2 mature larvae, same data as the Neotype, Cecid. Nos. B9102-B9105; 6 \mathfrak{P} , 3 puparia, galls collected from Nejime, Kagoshima pref., 22. VII. 1971, S. Hashimoto leg., host: *ibid.*, emerged on 31. VII. 1971, reared by J. Yukawa, Cecid. Nos. B9106-

papillae normal; sternal papillae without seta on all thoracic segments; inner pleural papillae without seta on prothorax, each with a seta on meso- and metathorax; usually 4 anterior ventral papillae without seta; 2 posterior ventral papillae each with a seta; 4 ventral papillae of eighth abdominal segment without seta; 4 anal papillae visible, each without seta.

Pupa: Unknown.

Host plant: Patrinia villosa (Thunb.) Juss. "Otokoeshi" [Valerianaceae].

Gall: Fruit transformed into a globular, succulent swelling with an apical protuberance; maximum diameter 6.7 to 17.2 mm, height 5.2 to 12.1 mm; surface smooth, pale yellow; monothalamus; each gall containing 1 to 60 larvae. Japanese name of the gall: "Otokoeshi-mi-fukure-fushi" Sunose¹¹⁾ (="Otokoeshi-mi-fushi" Monzen⁵⁾; Shinji¹⁰⁾; Yano¹³⁾; Yukawa¹⁶⁾).

Biological notes: This species may be normally univoltine. Newly produced galls containing young larvae are commonly observed throughout the summer season. According to Shinji^{7,10)}, larvae mature in fall and hibernate (probably in the soil), and adults emerge in May or June of the following year.

Slide-mounted specimens examined: Neotype \circlearrowleft , gall collected from Iôzan, Kanazawa city, Ishikawa pref., 17. X. 1978, J. Yukawa leg., host: *Patrinia villosa*, emerged on 22.IV.1979, reared by J. Yukawa, Cecid. No. C3201. (The emergence datum is earlier than normal one, because the larva was incubated at room temperature during the hibernation). 6 mature larvae, galls collected from Maruyama, Ojiya city, Niigata pref., 12.X.1981, K. Yamagishi leg., host: *ibid.*, Cecid. Nos. C3202-C3207.

Miscellaneous data of collection: 3 first ins. larvae (in alcohol), galls collected from Tomakomai city, Hokkaido, 5.IX.1977, J. Yukawa & S. Yamauchi leg., host: *Patrinia villosa*; several galls collected from Okushiri Is., Hokkaido, 6.X.1981, T. Sunose leg.¹¹⁾, host: *ibid*.

Distribution: Japan (Hokkaido, Honshu, Shikoku).

Remarks

The three species previously placed in the genus Asphondylia are newly combined with the genus Asteralobia in the present paper, because male genitalia and flagellomeres, and other morphological features of both mature and immature stages well coincide with the generic diagnosis of the genus Asteralobia⁴. As a result, the number of species belonging to the genus in Japan now stands at five, including the two previously known species, Asteralobia sasaki (Monzen)⁶ and Asteralobia soyogo (Kikuti)³ which produce bud galls on Ilex.

^{*}ds: distal stem, be: basal enlargement, w: maximum width of basal enlargement.

^{**}tarsomeres 2 to 5 could not be measured.

The humulus leaf gall midge, A. humuli is the smallest species among them and is characterized by the numbers of fronto-clypeal and thoracic setae (Table 1). This species is also distinguishable from A. sasaki and A. soyogo by the different arrangement of papillae on the larval and pupal surface: sternal papillae without seta on all thoracic segments and anterior ventral papillae without seta in A. humuli. (See Yukawa¹⁴⁾ for the descriptions of immature stages of A. sasaki and A. soyogo).

The styrax vein gall midge, A. styraci is the largest species and presents a striking contrast to A. humuli and to A. patriniae in the fronto-clypeal and thoracic setal counts (Tables 1 & 4).

The patrinia fruit gall midge, A. patriniae is easily separable from the four other Japanese species by having a distinct peak on post vertical portion and two to four rows of microtrichea on the distal stem of flagellomeres. In addition, this species is distinguished from A. humuli, A. sasaki and A. soyogo by the absence of two dorsal papillae between spiracles on the eighth abdominal segment of the mature larva.

A Russian species, Asteralobia patriniae Kovalev⁴⁾ has been known to produce fruit galls on *Patrinia scabiosifolia* and *Patrinia rupestris* in the Soviet Far East Region. The Russian species is morphologically quite similar to the Japanese A. patriniae and may possibly be synonymized with the latter. However, a detailed study must await the collection of further materials from Japan.

Summary

The three gall midge species previously placed in the genus *Asphondylia* are newly combined with the genus *Asteralobia*. These species, *A. humuli*, *A. styraci* and *A. patriniae* are redescribed together with the collecting data and some brief notes on their host plants, galls, biology and distribution.

Acknowledgements

The author would like to express his hearty thanks to Prof. A. Nagatomi (Kagoshima Univ.) for his critical reading of the draft. His thanks are also due to the following persons for their kindness in offering materials: Messrs. S. Hashimoto, K. Miyamoto, K. Nakagawa, Dr. T. Sunose, Messrs. S. Usuba, K. Yamagishi and S. Yamauchi.
