I INTRODUCTION

The forest in Kutai Nature Reserve (now national park) in East Kalimantan is known as the most developed and well reserved tropical rain forest dominated by many Dipterocarpaceous species in the world. For 11 months from 1982 to 1983 it has exposed an extreme desiccation without rain, and a large area of it caught fire and was burnt off besides limited areas in places of the reserve.

Tropical rain forests grow in the wet tropical lowland and are hard to catch fire. Misfortune in the case of Kutai Nature Reserve should be turned into a blessing. The way to the fortune is to make use of this golden opportunity for study given by nature. Detailed records in a stage of reforestation process may be useful for greening devastated tropical areas by synthesizing data to be obtained successive studies. In this connection we designed the present research plan in co-operation with the scientists of both countries.

Forest fire is the worst way of forest damages. The largest area damaged by the forest fire of the world is the Kalimantan fire covering 3.1 million ha. The second one is Penshtigo fire by which forests of 1.5 million ha were destroyed in 1871. Last year we had a news of big fire in Ta Hsing An Ling mountain range where mixed forests of birch and larch in one million ha were burnt to ashes. The pattern of forest damage and destroy is different from place to place. Climate, weather, and vegetation give an important role for the pattern of burning. It is our purpose to make clear the degree of forest damage in various places, pattern of forest recovery by seedlings or sprouts, and the process of increase in species diversity.

Identification of plant species from Kalimantan is quite difficult, because there are few knowledge on the flora of Kalimantan and our specimens collected from quadrats were almost

sterile. In the field identification was done firstly by WIRAWAN and OKA, and afterwards by Mr. Tukirin PARTOMIHARDJO, Junior Botanist in the Herbarium Bogoriense. Still there are many species in question. Because of the unfinished identification of plants and no ample time for full analysis of data, this paper will be revised in near future.

II METHODS

1 Description of study sites

Climate According to Kantor Statistik Propinsi Kalimantan Timur (1985) and Lembaga Meteorologi dan Geofisika (1983), annual mean rainfall from 1963 to 1980 is 2108mm, and the distribution of monthly mean rainfall from January to December and that in 1982 are shown in the followings.

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec	Total
Mean	187	181	201	165	192	157	103	148	119	128	169	220	2108mm
1982	396	163	158	46	133	138	0	66	73	29	24	43	1269mm

In every month rainfall is more than 100mm in the ordinary years, but in 1982 it was extremely lower than in the ordinary years (see also Fig. 1). We could not obtain meteorological data of 1983. The drought period from 1982-1983 was broken by a heavy shower in May 1983.

LEIGHTON and WIRAWAN (1985) discussed the climate of East Kalimantan based on the meteorological record for 44 years since 1940, and recognized 10 times of drought. Among them 9 were accompanied by El Nino phenomena in the East Pacific.

Geology According to WIRAWAN (1985) Kutai Basin was formed before Eocene. During Eocene and lower Oligocene this basin sank under the sea water by the crustal movement, and fine clay particles were sedimented at the top of the basin. The Kutai Basin uplifted again in connection with the movement of Sunda Shelf at the end of Oligocene. Oceanic sedimentation was gradually replaced by the deltaic sedimentation with coarser materials, and this activity reached maximum in upper Miocene to Pliocene. The oceanic sedimentation produced Pamaluan and Bebulu Formations, while the deltaic sedimentation made Pulau Balang, Balikpapan and Kampungbaru Formations. Quarternary Alluvium deposits are restricted to the beach area (Fig. 2).

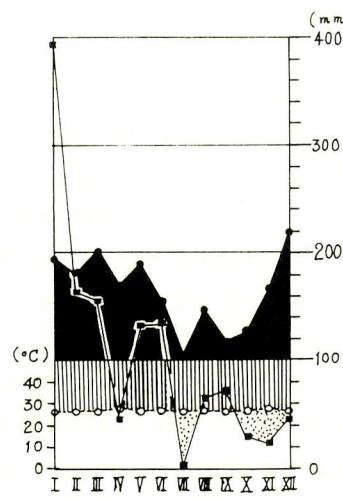

Fig. 1 Climate diagramme in Bontang
Squares and straight line show the
rainfall in 1982.

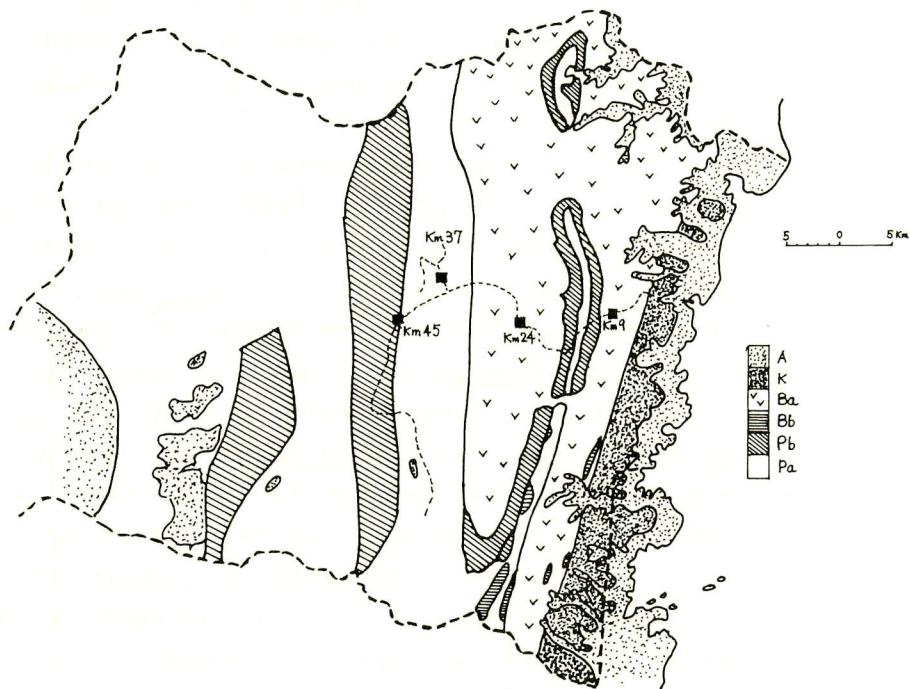

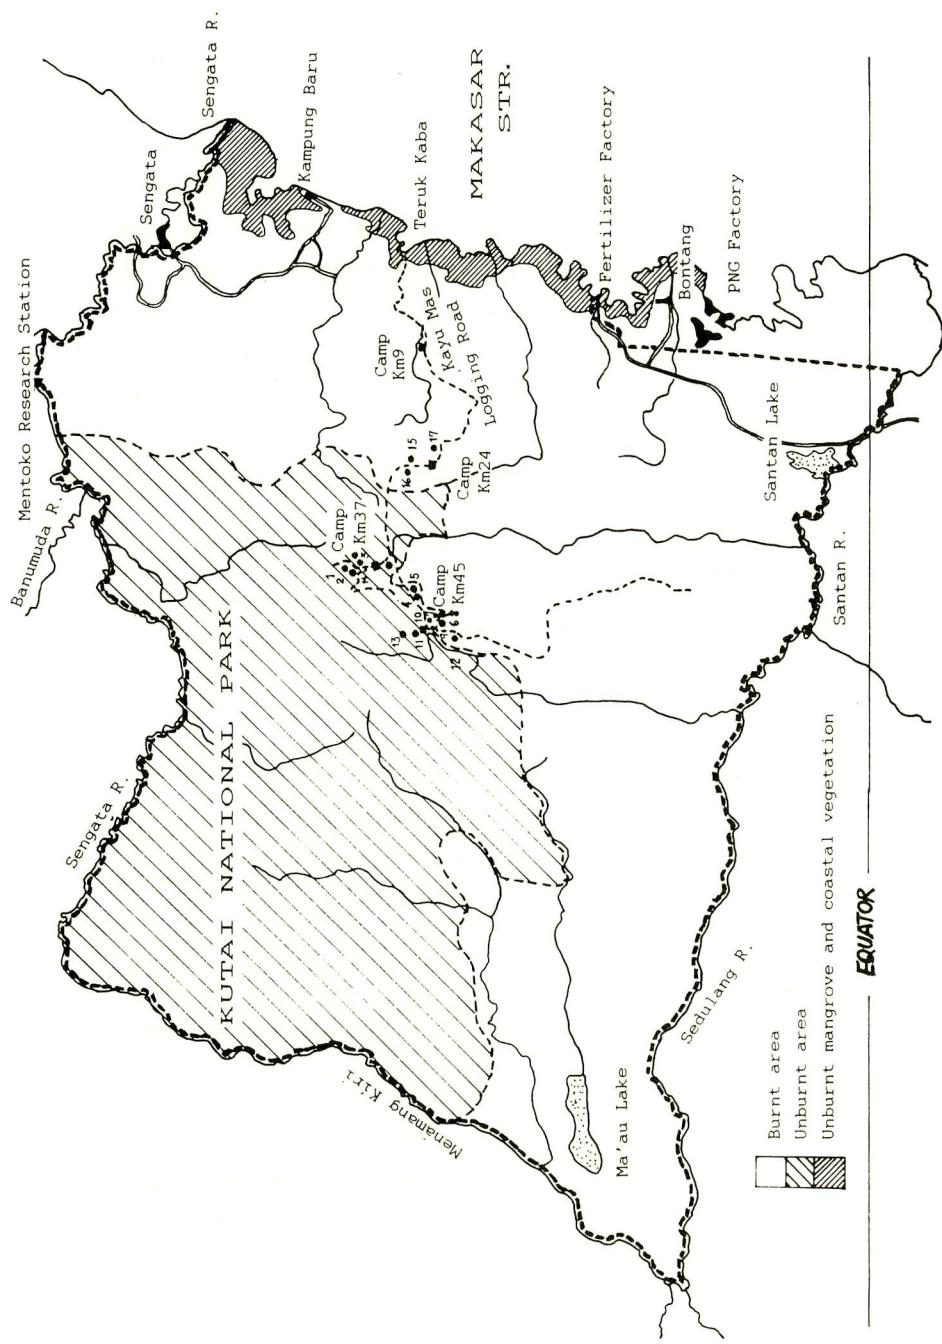

Fig. 2 Geological structure in Kutai National Park (WIRAWAN, 1985)
A: Alluvium deposits, K: Kampungbaru Formation, Ba: Balikpapan
Formation, Bb: Babulu Formation, Pb: Pulau Balang Formation, Pa:
Pamaluan Formation

Babulu Formation consisted mainly of limestone distributes primarily outside the park area. Kampungbaru Formation is intercalated between Balikpapan Formation and Alluvium and exposed on the coastal area. We did not established sample plots on these two formations, because vegetation (kerangas) on the latter was greatly damaged by logging as described above. Pamaluan Formation is consisted of silty and sandy claystone, and soils were muddy because of bad drainage. While, Pulau Balang Formation is formed with sandstone, and the water drainage of soils from weathered sandstone is better than those from mud stones. Balikpapan Formation is consisted of alternated strata of sandstone and mudstone. Coal seams to a thickness of a few feet were intercalated in this formation, and exposed on the ground surface. The coal caught fire and continued to produce smoke after extinction of forest fire.

Topography The Kutai Basin has nearly flat and undulate topography with solitary peaks in places (the highest peak is 397m at the top of Tandung Mayang Mountain). The geological structure runs north and south, and the undulation runs parallel to the shore. The Kutai Park is enclosed with rivers; Sengata River in the north, Menamang Kiri River in the west, and both Sedulang and Santan Rivers in the south. Bontang and its outskirt were excluded from the park.

Vegetation Kutai National Park occupies 320,000ha in East Kalimantan, and was covered by the following six types of vegetation (WIRAWAN, 1985); mangrove in the beach areas, fresh-water swamp forest dominated by Eugenia, "kerangas" (tropical heath forest), "ulin- meranti-kapur" (Eusideroxylon zwageri-Shorea spp.-Dryobalanops spp.) forest, mixed dipterocarp forest and flood plain forest characterized by Octomeles sumatrana, Pterospermum spp. and Barringtonia sp. Mangrove and fresh-water swamp were litte damaged by 1983 fire. Kerangas forest occurs at the foot-hills west of Teruk Kaba and in the Menamang area, and was damaged intensively by logging activities preceding the drought and fire. In this circumstance we did not set up sample plots in those two types of forests.

In eastern part of the park from the beach to the fire front (Fig. 3) there is a network of logging road made by several companies. The forest damage was heavier on the roadside than distant places from the road, because there were a heap of logs and branches and low and young trees which had been germinated

after logging on the roadside.

2 Sample plots

We established 4 camps (at Km9, Km24, Km37 and Km45) on Kayu Mas Road. At the camp Km37 (at 37km from the shore in Teruk Kaba) there was logging huts left behind withdrawal from lumbering activity, and we used them as the base camp. It is desirable to establish plural quadrats in unburnt forest stands in each geological formation, but there is no time for setting up so many quadrats. In addition, on Balikpapan Formation it was difficult to find forest stands not affected by fire. Therefore, our search for unburnt forest stands was focused only on Pamaluan and Pulau Balang Formations but not for stands of subsere. General description of quadrats is given in Table 1.

Table 1. General description of quadrats

Asterisks indicate the quadrat in the unburnt forest stand. As to geological marks, Pa, Pb and Ba, see Fig. 2. Dominants in the table were recognized by the largest basal area shown in Tables 2 - 23.

Quadrat number	Altitude (m)	Slope exposure	Inclination (°)	Size (m ²)	Geology	Dominants
1*	185	S	7-15	40x50	Pa	Shorea spp.-Eusideroxylon zwageri
2*	166	N50E	16	40x50	Pa	Eusideroxylon zwageri-Pithecellobium sp.
3	150	0	0	20x20	Pa	Anthocephalus chinensis-Macaranga pruinosa
4	324	N45E	8	20x20	Pa	Homalanthus populneus
5	280	S45E	20	15x30	Pa	Croton argyratus
6	245	S	20	40x50	Pb	Borassodendron borneensis-Eu. zwageri
7	280	N40E	8-24	20x30	Pb	Glochidion capitatum-Mallotus macrostachyus
8	230	N,N10W	8-18	10x30	Pb	Melastoma malabathricum, Duabanga moluccana
9	240	N40E	10	10x10	Pb	Macaranga trichocarpa
10	220	N80E	25	20x20	Pb	Eu. zwageri-Macaranga pruinosa
11*	200	N52E	16	40x50	Pb	Dryobalanops sp.
12	230	N22E	12-15	20x20	Pb	Macaranga gigantea
13*	210	N67W	10	40x50	Pb	Dryobalanops sp.-Shorea polyandra
14	150	0	0	20x20	Pa	Macaranga pruinosa-Eu. zwageri
15	280	N22E	10	10x20	Ba	Tristania whitiana
16	280	S67W	13	10x20	Ba	Evodia alba-Macaranga gigantea
17	200	0	0	5x15	Ba	Shorea leprosula-Macaranga gigantea

The distribution of the quadrats is shown in Fig. 3. The quadrats were concentrated to areas near the camps because of saving time. The size of the quadrats was determined by the area of forest stands and the height of trees.

In every quadrat the following characters were recorded; diameter at breast height (DBH), height (H) of trees, the number of sprouts and their size (H and DBH when H was longer than 130cm), the number of seedlings, saplings and herbaceous plants (or the number of shoots in case of indefinite individuality) including ferns. In some quadrats forest profiles and crown projection diagrammes were drawn on the section paper.

In the subseral forests in the damaged area, quadrats were set up in the relatively homogenous stand. White and rotten truncks were stood high swinging in the wind and were falling down with the heavy thud.

III RESULTS

Results after simple analysis of the data is shown in Tables 2-23. In the tables, the following attributes are shown; the number of individuals, mean and maximum DBH, maximum height of the trees, basal area (DBH^2), and volume ($DBH^2 \times H$) in each species.

Plant sociological analysis based on the tentative species identification is given by Miyagi et al in this report. As the classification of forest types based on the similarity of species composition is not yet carried out, there is a risk for describing community types in the present stage of research. However, we recognized three types of natural forest in the unburnt area; Shorea forest and Eusideroxylon forest on Pamaluan Formation and Dryobalanops forest on Pulau Balang Formation. YAMAKURA et al (1986) reported Shorea cf. laevis forest from Sebulu near Samarinda, East Kalimantan. RISWAN AND KENWORTHY (1984) discussed the source and fate of Shorea polyandra-S. ovalis forest and secondary forests in Lempake near Samarinda. MIYAWAKI et al (1982) recognized a few types of plant communities in Sotek near Balikpapan on the standpoint of BRAUN-BLANQUET system. From these papers we know that there are a number of forest types in a limited area of lowland Kalimantan Timur (East Kalimantan Province).

Although those three types of forest we recognized were lightly influenced by 1982-3 drought, we used them as the control of subseral communities. The prominent trees reached more than 60m, and a few strata were recognized.

The degree of damage by fire varied whether timbers had cut down before the fire or not. In the place where logging had been done before the fire, there were many types of regrowth vegetation on the forest floor with woods, branches and dry leaves in disorder. In such a place fire burned down everythings leaving denuded ground. We witnessed such a case along the Kayu Mas logging road. Along the both side of the road there were nearly pure stands dominated with secondary tree species, such as Anthocephalus chinensis, Homalanthus populneus, Glochidion capitatum, Macaranga trichocarpa, M. gigantea, Croton argyratus, Tristania whitiana, Mallotus spp. and so on. These secondary species also appeared in the open of the forests with a little damage by the fire, but seldom in undisturbed forests. To answer the purpose of this research, sample plots were selectively set up in such a pure stand of subsere as described above.

Lightly damaged forest stands (cf. photos on the frontispiece) were widely distributed in the eastern and southern part of the park. There the fire swept away undergrowth vegetation as well as dry litter on the floor. Only the tall trees wound round by lianes caught fire at their crown. Some emergent trees over 50m and lower ones were stood alive, and shrub layer was occupied by the subseral species described above. Near the topographic depression such as rivers and ravines a number of original plants were alive and were vigorously growing. A palm species, Borassodendron borneensis, and Eusideroxylon zwageri were strongly resistant to fire. Only the latter species sprouted at the base of a trunk. There were no other tree species which produce sprouts around the dead trunk, but for the secondary species.

Eu. zwageri produces not so many but larger fruits. On A333 tree in P-3 quadrat, for example, more than 107 fruits were counted, 31 were dead and rotten and only one were germinating. Fruits of the same species were not observed even on the trees and on the floor in the burned area. Two exceptions were observed by Parinaria sp. (Rosaceae) and Bor. borneensis. Both species produce a large fruits with hard and thick seed coat.

In the present stage of data analysis, it is impossible to derive further discussion and some conclusions. We will wait for the advanced analysis of data, and this paper will be revised in near future.

Successive or intermittent observations of recovering forest are necessary to realize our purpose.

Herb: Herbarium number. Fam: Family. No: No of trees in the plot.

BA: Basal area (Summed area of stem cross sections at height of 1.3m) DDH: Sum of DBH x DBH x H

Same species name of different Herbarium number: not sure to be the same.

Species name with spp.: not only one species.
