# The Oceanographical Research in the Southern Region of the Hawaiian Islands-V 

Yasutaka Yuwaki*, Kiyoshi Shimada*, Masataka Higashi* and Tomio Henmi*

#### Abstract

The oceanographical observations were made by the Keiten Maru in the southwestern waters of the Hawaiian Islands in May and June, 1981, and in May, 1982. In 1981, the remarkable upwelling was found at $20^{\circ} \mathrm{N}, 163^{\circ} \mathrm{W}$, and the strong current flows southward at the eastern side of the upwelling area with a maximum velocity of about $40 \mathrm{~cm} / \mathrm{sec}$ or more. The North Equatorial Current was found at south of $17.5^{\circ} \mathrm{N}$ along the meridional section of $166^{\circ} \mathrm{W}$. It's current velocity was $15 \mathrm{~cm} / \mathrm{sec}$ and it was slower than that of the northward and the southward flows on the latitudinal section of $20^{\circ} \mathrm{N}$. In 1982, no remarkable feature of oceanic structure was found along the latitudinal section of $20^{\circ} \mathrm{N}$.

## 1. Introduction

In successive four years since summer of 1977, the Keiten Maru (G.T 860 ton), training ship of the Kagoshima University, made the meridional oceanographic sections along the meridians of $156^{\circ} \mathrm{W}$ and $158^{\circ} \mathrm{W}$ in the southern region of the Hawaiian Islands. The general features of oceanic conditions along these sections on May and June of four years, 1977-1980, were already reported in the previous papers (Yuwaki and Henmi, 1978, 1979, 1980, 1981). In summer of 1981 and 1982, the oceanographical observations were carried out by the Keiten Maru in the southwestern waters of the Hawaiian Islands to investigate relation between the tuna-fishing condition and the oceanographic one, concurrently with the training of cadets. Some oceanographic informations obtained on the bases of their data are reported here.

## 2. Observations

In 1981, the two oceanographic sections were made, the one was along the parallel of latitude of $20^{\circ} \mathrm{N}$ between $160^{\circ} \mathrm{W}$ and $168^{\circ} \mathrm{W}$ on May $9-19$, the other was along the meridian of $166^{\circ} \mathrm{W}$ between $15^{\circ} \mathrm{N}$ and $20^{\circ} \mathrm{N}$ on June 4-9. In 1982, it was along the parallel of latitude of $20^{\circ} \mathrm{N}$ between $160^{\circ} \mathrm{W}$ and $173^{\circ} \mathrm{W}$ on May $10-18$. The observation stations are shown in Fig. 1. The S.T.D cast down to $1,200 \mathrm{~m}$ at every stations.

The values of water temperature and salinity read from S.T.D recorders are tabulated in

[^0]Appendix 1. Some direct current measurement by G.E.K were carried out at several stations.

Fig. 1. Oceanographic stations of S. T. D observations in the southwestern waters of the Hawaiian Islands.
circles, 1981; cross, 1982.

## 3. Temperature

The vertical distributions of temperature on the section of $20^{\circ} \mathrm{N}$ and $166^{\circ} \mathrm{W}$ in May and June, 1981, and on the section of $20^{\circ} \mathrm{N}$ in May, 1982 are shown in Fig. 2,(a), (b), (c), respectively. On the section of $20^{\circ} \mathrm{N}$ in 1981 (Fig. 2, a), the remarkable convex pattern of the isotherms is found near $163^{\circ} \mathrm{W}$ and a good indicator of the boundary of strong current between the northward and the southward flow, it seems to be the upwelling take place. The thermocline is found in a layer between about 50 m and 350 m depth. It is shallowest at $163^{\circ} \mathrm{W}$ and the vertical gradient of temperature is largest here reaching about $0.05^{\circ} \mathrm{C} / \mathrm{m}$. The temperature decreases very slowly with depth below about 400 m , and it is about $4.0^{\circ} \mathrm{C}$ in a layer of $1,100 \mathrm{~m}$ depth. On the section of $166^{\circ} \mathrm{W}$ in 1981 (Fig. 2, b), the temperature in the surface mixed layer is about $26^{\circ} \mathrm{C}$ or more, being gradually increases toward the south. The large slope of the isotherms is found near $16^{\circ} \mathrm{N}$ corresponding to the North Equatorial Current. The largest vertical gradient of temperature is about $0.08^{\circ} \mathrm{C} / \mathrm{m}$ at $16^{\circ} \mathrm{N}$ and it is larger than that at $20^{\circ} \mathrm{N}$. The isotherms slope slightly up from $18^{\circ} \mathrm{N}$ toward the north below about 500 m , which may indicate the upwelling of the lower water. On the section of $20^{\circ} \mathrm{N}$ in 1982 (Fig. 2, c), the large slope of the isotherms is found near $170^{\circ} \mathrm{W}$ corresponding to strong current, and the largest vertical gradient is found near $166^{\circ} \mathrm{W}$ having a value of about $0.06^{\circ} \mathrm{C} / \mathrm{m}$ and seems to be indicate the existence of weaker upwelling.

Fig. 2. Temperature sections on the $20^{\circ} \mathrm{N}$ line (a) and on the $166^{\circ} \mathrm{W}$ line (b) in 1981 , on the $20^{\circ} \mathrm{N}$ line (c) in 1982.

## 4. Salinity

The vertical distributions of salinity on the section of $20^{\circ} \mathrm{N}$ and $166^{\circ} \mathrm{W}$ in May and June, 1981, and on the section of $20^{\circ} \mathrm{N}$ in May, 1982 are shown in Fig. 3, (a), (b), (c), respectively. On the section of $20^{\circ} \mathrm{N}$ (Fig. 3, a), the salinity maximum waters more than $35.20 \%$ comes from the Subtropical region are found in a layer of about 100 m depth at the east of $162^{\circ} \mathrm{W}$ and the west of $165^{\circ} \mathrm{W}$. There is no salinity maximum water at $163^{\circ}-164^{\circ} \mathrm{W}$, where the upwelling is suspected to have take place in the temperature section. On the section of $166^{\circ} \mathrm{W}$ in 1981 (Fig. 3, b), the salinity maximum water of about $35.00 \%$ extends toward the south in the surface layer and it reaches to near $17^{\circ} \mathrm{N}$, the boundary between the eastward flow and the westward flow. The salinity maximum water has become gradually deeper toward the south and its depth is about 150 m near $17^{\circ} \mathrm{N}$. According our observations between 1977 and 1980 , the salinity water of about $35.00 \%$ was found at a depth of about 200 m near $15^{\circ} \mathrm{N}$ in the meridional section of

Fig. 3. Salinity sections on the $20^{\circ} \mathrm{N}$ line (a) and on the $166^{\circ} \mathrm{W}$ line (b) in 1981 , on the $20^{\circ} \mathrm{N}$ line (c) in 1982.
$158^{\circ} \mathrm{W}$. North of $19^{\circ} \mathrm{N}$, a salinity minimum with a salinity less than $34.20 \%$ associated with the North Pacific Intermediate Water is found in a layer between 400 m and 500 m depth. The salinity minimum extends slightly upward to the south in a layer between 300 m and 400 m depth, and a part of salinity minimum reaches to near $15^{\circ} \mathrm{N}$. On the section of $20^{\circ} \mathrm{N}$ in 1982 (Fig. 3, c), the low salinity less than $34.50 \%$ is found in the surface of the east of $166^{\circ} \mathrm{W}$, but it was not found in 1981. The salinity maximum waters more than $35.20 \%$ are found in a layer of about 100 m depth at the east of $164^{\circ} \mathrm{W}$ and the west of $168^{\circ} \mathrm{W}$, and it is shift to the west about 150 miles compared with that in 1981.

## 5. Geostrophic Current

The geostrophic current are computed referred to $1,200 \mathrm{~m}$ depth. The velocity distributions on the section of $20^{\circ} \mathrm{N}$ and $166^{\circ} \mathrm{W}$ in May and June, 1981 , and on the section of $20^{\circ} \mathrm{N}$ in May,

Fig. 4. Velocity sections at $20^{\circ} \mathrm{N}$ (a) and $166^{\circ} \mathrm{W}$ (b) in 1981 and at $20^{\circ} \mathrm{N}$ (c) in 1982.

1982 are shown in Fig. 4, (a), (b), (c), respectively. The current speeds on the latitudinal section are larger than that on the longitudinal section. The maximum speeds of the northward and the southward flow are about 0.7 knot at $163^{\circ}-30^{\prime} \mathrm{W}$ and 1.0 knot at $162^{\circ}-30^{\prime} \mathrm{W}$ in 1981 (Fig. 4, a), 0.4 knot at $168^{\circ}-30^{\prime} \mathrm{W}$ and $169^{\circ}-30^{\prime} \mathrm{W}$ in 1982 (Fig. 4, c). The maximum speeds of the westward and the eastward flow are about 0.3 knot at $16^{\circ} \mathrm{N}$ and 0.4 knot at $18^{\circ}-30^{\prime} \mathrm{N}$ (Fig. 4, b). The westward flow is the North Equatorial Current and the eastward flow may be the Subtropical Counter-Current which was showed by Yoshida et al (1967). Based on the G.E.K observations in Fig. 5, (a) and (b), the surface current along the latitude of $20^{\circ} \mathrm{N}$ between the longitude of $167^{\circ} \mathrm{W}$ and $173^{\circ} \mathrm{W}$ flows to the east with a maximum velocity of 0.9 knot and it turns to the south near $165^{\circ} \mathrm{W}$. Then, it flows to the south-southeast with a maximum velocity of about 1.4 knot and most parts of it flows to the southwest near $18^{\circ} \mathrm{N}$ and go round on the righthand side of the Johnstone Islands.

## 6. Summary

The oceanographical researchs were carried out in the southwestern region of the Hawaiian Islands in May and June, 1981, and in May, 1982. The remarkable upwelling was found at $20^{\circ} \mathrm{N}, 163^{\circ} \mathrm{W}$ in 1981 but it was obscure in 1982. The salinity maximum waters came from the north with a salinity of about $35.20 \%$ were separated two portions owing to the upwelling phenomenon. There were no salinity maximum waters at $163^{\circ}-164^{\circ} \mathrm{W}$ in 1981 and $165^{\circ}-167^{\circ} \mathrm{W}$ in 1982 . The current along the parallel of latitude of $20^{\circ} \mathrm{N}$ flows from $173^{\circ} \mathrm{W}$ to the east and it turns to the southward near $165^{\circ} \mathrm{W}$. Then, it flows to the south with a maximum velocity of about $40 \mathrm{~cm} / \mathrm{sec}$ and joins to the North Equatorial Current. The main axis of the North Equatorial Current was located near $16^{\circ} \mathrm{N}$ with a maximum velocity of about $15 \mathrm{~cm} / \mathrm{sec}$.
The maximum velocity of the North Equatorial Current are smaller than that of the southward flow.

## Acknowledgment

The authors wished to express his hearty thanks to Dr. M. Chaen of Kagoshima University for kind guidance and encouragement.
